About Emerald www.emeraldinsight.com

Emerald is a global publisher linking research and practice to the benefit of society. The company manages a portfolio of more than 290 journals and over 2,350 books and book series volumes, as well as providing an extensive range of online products and additional customer resources and services.

Emerald is both COUNTER 4 and TRANSFER compliant. The organization is a partner of the Committee on Publication Ethics (COPE) and also works with Portico and the LOCKSS initiative for digital archive preservation.

Abstract

Purpose – The purpose of this paper is to support the use of unique identifiers for the authors of scientific publications. This, the authors believe, aligns with the views of many others, as it would solve the problem of author disambiguation. If every researcher had a unique identifier, there would be significant opportunities to provide even more services. These extensions are proposed in this paper.

Design/methodology/approach – The authors discuss the bibliographic services that are currently available. This leads to a discussion of how these services could be developed and extended.

Findings – The authors suggest a number of ways that a unique identifier for scientific authors could support many other areas of importance to the scientific community. This will provide a much more robust system that provides a much richer and more easily maintained, scientific environment.

Originality/value – The scientific community lags behind most other communities with regard to the way it identifies individuals. Even if the current vision for a unique identifier for authors was to become more widespread, there would still be many areas where the community could improve its operations. This viewpoint paper suggests some of these, along with a financial model that could underpin the functionality.

Keywords Publishing, Author disambiguation, Unique identifiers

Paper type Viewpoint

1. Introduction

Like many other industries, scientific publishing is going through a revolution, largely brought about by the ever-increasing functionality of the internet. The business model that underpins scientific publishing is seeing significant changes, primarily led by the move towards open access publishing (Collins, 2005; Ennas and Di Guardo, 2015; Masrek and Yaakub, 2015; Rodriguez, 2014).

While the internet has brought significant advantages, it has also led to new challenges. A significant challenge is author disambiguation (Chin *et al.*, 2014; Ferreira *et al.*, 2012; Kawashima and Tomizawa, 2015; Liu *et al.*, 2015; Shoaib *et al.*, 2015), which has become an issue, as access to papers through an electronic medium has become possible. Automatic processing of authors' names while attempting to collate all the papers for a given author using just the text version of their names is a challenging problem. Typical issues include authors' changing names (e.g. through marriage), using different versions of an author's name (e.g. inclusion, or not, of their initials), affiliation with different institutions, the use (or not) of accented characters and so forth. Until recently, the only way to identify an author was by using the text used to write their name. In recent years, some tools have become

available that enable a unique identifier to be assigned to a given author. If this had widespread adoption, it would not only solve the author disambiguation problem but could also open up a range of other opportunities which are not currently easily available to the scientific community. That is, it would not only resolve the author disambiguation problem but also provide many added value benefits, which are not available at the current time.

In this viewpoint article, the authors propose that all researchers should have a unique identifier that is used to identify themselves. The industry needs to agree on just one standard and all publishers/researchers should be encouraged to adopt that standard. Indeed, it would be best to get to a position where peer pressure and normal working practices ensure that researchers see the benefit of adopting a unique ID for their professional persona.

Having a unique identifier might also be a condition of publishing in the peer-reviewed scientific literature and that this ID should be included in the workflows of scientific publishers. In 2016, seven publishers announced that during 2016, they would require authors to use an ORCID ID if they wished to publish[1]. The authors support this initiative.

The ideas presented in this article would require publishers to agree to some basic standards and to agree to work together, possibly through an independent intermediary. Moreover, it would require the academic community to agree to also work within the proposed structure, many of which already do, to get the benefits from the proposals in this paper.

The remainder of this paper is structured as follows. In the next section, the motivation behind having a single author identity is drawn out and some of the challenges in reaching this goal are highlighted. In Section 3, the current provision with regard to scientific publishing is discussed, drawing out the shortcomings with the current model (Section 4). In Section 5, the benefits of adopting a common standard are discussed. A proposed financial model is presented in Section 6 so that any system is sustainable. In Section 7, the authors state their proposals, and they challenge the scientific community to adopt them. Finally, a closing discussion is presented and the paper is concluded in Sections 8 and 9, respectively.

2. Motivation

In almost every aspect of our lives, we have a unique identifier so that we can be unambiguously identified. Whether that is a student/staff ID, a bank account number, a customer reference number for a utility company, a customer number for online services and so forth, you are little more than a number inside an IT system. Indeed, one of the main principles that underpin any database is that each record should have a unique identifier. Whether you recognise it or not, every time you register for any type of service, you will be assigned a unique identifier.

Indeed, this will happen when researchers create an account with a journal. The unique identifier is likely to be a name that the user chooses, or their e-mail address. However, this leads to a twofold problem:

- (1) each user may have different services (e.g. journals) that they use; and
- (2) they will have a different identifier on different services, with no way of being able to link them.

Finding ourselves in this position is not a surprise, as the scientific publishing industry has evolved over hundreds of years, rather than being consciously designed. The rise of the internet has highlighted the limitations of the current model.

Having said that, there is evidence that the industry is able to come together to improve the system. The digital object identifier (DOI) (Chandrakar, 2006) system was introduced in

1997[2]. This system is a way of uniquely identifying a scientific paper. Importantly, it also provides a persistent URL so that once you know the DOI, you can access a paper using a URL of the form <http://dx.doi.org/DOI>. Where the paper is actually located is of no concern, as long as the underlying DOI system is updated when the owner relocates the paper. Since the DOI system was introduced, many papers (if not the majority) that were published prior to its introduction have been classified. It is even possible to locate Einstein's (1905) seminal paper on special relativity using its DOI (10.1002/andp.19053221004[3]).

If we could get to a position where every academic had a unique identifier, it would eliminate the problem of author disambiguation. There have been some notable attempts to do this (see Section 3), and these are still ongoing. However, in our view, without five key criteria being met, the aim of scientists having a unique identifier is still a long way off. These criteria are as follows:

- (1) Every academic should be encouraged to have a unique identifier that is persistent throughout their academic career.
- (2) There should be one standard, rather than many, often-competing, standards.
- (3) Publishers should build any system into their workflows.
- (4) The data should be maintained by a not-for-profit organisation and not be held by any one publisher or company.
- (5) There should be a sustainable financial model underpinning any initiative.

Others have promoted the use of single author identification. Qiu (2008) outlines the problems faced by Chinese authors in particular. It is interesting to see just one of the problems faced by this community. Qiu (2008, p. 766) says:

Chinese researchers adopt a phonetic version of their names, converted through the pinyin Romanization system, which uses the Latin alphabet to represent sounds from Chinese. This approach, however, is not bi-directionally unique. There are two Chinese surnames that can be "spelt" as Wang, for instance. And the problem is compounded by the sheer number of Chinese researchers who have not just the same surname, but also the same initial. Searching the biomedical-literature database PubMed, curated by the USA National Library of Medicine, for articles published by "Wang X" results in 8,904 entries, and this number rises almost daily.

But this is just one complexity, and others are presented in the article.

3. Current services

The publishing industry provides a range of services for the scientific community to maintain and monitor scientific articles. These are usually provided free of charge to the end user, recognizing that the service provider will have access to the (potentially valuable) data. These services enable researchers to record their papers in a central repository, enabling them to keep track of their own papers, as well as locating the papers of their colleagues. The system may also suggest papers that you may have authored, and other authors will suggest papers that you have co-authored. Social media services may also be incorporated, as well as access to limited analytics, such as the number of citations, the number of downloads, h-indices and so forth. Some of the most well-known providers are ResearchGate[4], ResearcherID[5] and Google Scholar[6].

There are even services which cross sector boundaries. The International Standard Name Identifier (ISNI)[7] is an ISO (27729) certified standard for "identifying the millions of contributors to creative works and those active in their distribution, including researchers, inventors, writers, artists, visual creators, performers, producers, publishers, aggregators, and more" that aims to have "a persistent unique identifying number to resolve the problem

of name ambiguity". This is exactly in line with the aims of many of the other services provided in this paper. As far as the authors are aware, ISNI has not seen strong adoption within the scientific community, even though one of the authors of this paper was surprised to learn that they do have an ISNI identifier. Other services, such as Ringgold[8], aim to provide a unique identifier for institutions, for many of the reasons mentioned in this paper.

As far as the authors of this paper are aware, the service that has the highest level of integration with publisher workflows, albeit only partially, is ORCID. On some publishers' websites, you can register your ORCID ID and this will then be associated with any papers that you write. There has been some work in promoting the wider use of ORCID. Thomas *et al.* (2015) discuss how ORCID can be used, presenting case studies from the Modern Languages Association and Texas A&M University. The paper is enthusiastic about the wider take-up and usage of ORCID, but also notes several issues about wider uptake. A useful historical reference to ORCID is available from Anon (2009) and Butler (2012), with another good overview of ORCID being provided by Haak *et al.* (2012).

There are some other services starting to appear which enable different aspects of an academic's work to be registered. Publons[9] is one such example, which enables academics to store details of their peer-review activities.

Institutions increasingly want to capture data about their staff, in addition to details on their publications. There are providers that provide this functionality, such as Pure[10], Worktribe[11] and Converis[12]. These platforms are aimed at institutions that wish to collect and analyse data on the research activities of their staff. The data that can be stored include information about funding, conference attendance, peer review activity and so on.

Individuals may also have access to the data, but this assumes that the institution is using the platform. If an individual moves to a new institution, then access to the data may be lost or may have to be re-entered into the system used by the new institution.

As far as we are aware, there is no personal, free platform that enables an individual to store all their academic record in a way that is easily accessible to both the individual concerned and to the wider community. At least, there is no single system that provides this functionality using a single unique ID which is integrated into workflows.

4. Key issues

The key issues that we believe are present in the current system are as follows.

- (1) There are various systems (as outlined in Section 3), meaning that:
 - Academics have to register themselves on different systems.
 - Academics have to maintain their information on different systems.
 - Each system will have a different way of being updated.
 - There is little, or no, interaction between the various systems.
 - As a result of having different systems, researchers will have a number of different unique identifiers.
 - When trying to track down other research, a number of systems will need to be searched to find out the information needed.
 - Many of the systems are fundamentally commercially motivated, meaning that some collected data may not be available to anybody who wishes to access them.
- (2) Current systems, at least those that are publicly available, can only be utilised for tracking publications. They generally do not provide other functionalities which might be possible by leveraging a single unique identifier for every researcher.

- (3) The current systems compete with each other and, while there are benefits to them in collecting data, advertising and so on, they do not provide the scientific community with the services that it requires.

5. Potential benefits

If we were able to arrive at a position where every member of the academic community had a unique identifier aligned with one provider, it would provide the community with significant value. The most obvious benefit is that the author disambiguation problem would disappear. Other benefits could include (but certainly not be limited to) the following:

- *Common pool of reviewers:* At the present time, every publisher (at best) or journal maintains its own pool of reviewers. This is not only wasteful in terms of scientists having to maintain numerous accounts, but many potential reviewers will not be immediately available, unless they have previously published, or reviewed, for that journal/publisher. If there was a single pool of reviewers, this would have the benefit that scientists would only have to maintain a single system but every journal, and potentially conference, would have access to many more reviewers than they currently do.
- *Access to reviews undertaken:* Many scientists like to keep a record of reviews they have carried out, or at least the journals they have reviewed for. This is especially important for early career researchers who present this information as part of their growing international esteem. If these data were stored as part of a scientist's unique ID, then these data would be easily accessible.
- *Conference attendance:* Having a central repository would enable conference organisers to register their delegates via their unique ID. These data would then be available to recall who attended a given conference and which conferences have been attended by a given scientist.
- *Analysis:* Having data in a central repository would make analysis a lot easier and more meaningful (subject to privacy settings). For example, at the present time, we do not really know when an author started publishing, so it is difficult to compare one author with another with regard to (for example), the average number of papers published since they were awarded their PhD, average number of papers published each year of their career and so forth. If we had access to this data, it would be a lot easier to carry out analysis for different authors, different institutions and so on.
- *Produce CVs:* If an academic's data were maintained in a central repository, indexed by a unique ID, the database could be accessed to provide data for their curriculum vitae (CV).
- *API:* If an application programming interface (API) was developed, it would enable access, by a variety of agencies (funding agencies, individuals, institutions, etc.), to the underlying data. This would enable easy maintenance of websites, assist in promotion and job applications, assist in funding decisions and so on.
- *Programme committee membership:* Conferences could register their programme committee members with a central service. This could then provide details about people, conferences and so forth.
- *DOI integration:* If the DOI system could be integrated with the author ID system, this would provide benefits that are simply not possible at the moment. It would be easy to produce a list of papers for each co-author, it would be easy to produce a list of authors

who are publishing in similar areas, who have published with authors within n degrees of freedom of a given author and so forth.

Just a number

- *Author permalink*: In the same way that every paper has a permalink, if every academic had a unique ID, then they could also be associated with a permalink, so just knowing the ID for an academic would enable you to access all their (public) information.
- *Governments*: Many governments would like to track research that they fund and/or is carried out in their country. If the metadata associated with each author included their affiliation/country, this would enable a suitable API to return various data, rather than embarking on a major data-collection exercise.
- *Funding agencies*: Funding agencies, for example, Research Councils UK[13], have an interest in tracking the research undertaken on their behalf. The UK has recently initiated a programme[14] where all their funded research outputs are reported. Researchers are asked to store an ORCID ID as part of their profile, though it is not clear how integrated this is into the workflow.
- *Research assessment exercises*: Many countries regularly carry out research assessments of their universities and research institutions. The UK, for example, has the Research Excellence Framework (REF)[15] and Malaysia has the Malaysia Research Assessment (MyRA). These assessment instruments could benefit if every researcher had a unique identifier, along with suitable metadata.
- *Single login*: Perhaps the biggest benefit is that every researcher would have a single login to maintain their data. This not only saves time, but also ensures data consistency. For example, if a researcher marked themselves as being unavailable for reviewing, this information would be available to all journals. If they decided that their keywords were incorrect, then a single change would be available to all journals.
- *Research data*: If the data were made available to the scientific community, then it would enable many research projects to be undertaken. For example, what universities carry out most reviews, do some researchers mark themselves as permanently unavailable to carry out reviews, are there are differences across different disciplines and so on. The data held would be a rich repository for research projects, which can only be imagined at the moment.
- *Financial leverage*: Although we would expect the data to be freely available to those who wished to access them, there could be opportunities to provide consultancy services for interested parties who wished to have the data analysed by suitably qualified analysts.

353

6. Financial sustainability

If the proposals in this paper (see Section 7) were adopted, there would inevitably be questions about how it would be funded. There are some obvious options, such as asking the publishers, asking one or more professional bodies or user groups, or trying to fund it through advertising and sponsorship. None of these is ideal due to potential conflicts of interest and the reliance on ongoing support, which may not be forthcoming. The proposals would need the support of publishers, professional bodies, and societies, but that should, in our view, stop short of financial support.

One possible financial model would be, based on the concept that everybody who publishes has to pay, by an annual micro-payment. This payment could be as low as US\$5

per annum. There could also be different rates for developing countries, institutional subscriptions and so forth.

A conservative estimate^[16] places the number of active researchers at 15 million worldwide. If each of those paid US\$5, this would generate an annual income of US\$75m. This may seem a lot, but the start-up costs would be substantial, and there would be ongoing costs for staff, premises, technical resources (e.g. servers), development costs, sales and marketing, raising awareness, ensuring data integrity and so forth.

Adopting this policy would have the added advantage that the system would have the details of every active researcher, along with a history of previously active researchers, which would provide added value to the data that are stored and the analysis that can be performed.

7. Proposal

If the ideas in this paper are to become a reality, we would encourage adoption of the following proposals:

- The publishing and scientific community should agree to adopt a single standard to uniquely identify members of the scientific community.
- Every academic should have a unique identifier. This should not be reused when they are no longer active (either through retirement or death).
- Organisations (e.g. universities, funding agencies, government agencies, publishers, etc.). Should also have an identifier, which would provide a way to more easily access researchers of interest to them.
- Every academic should be strongly encouraged to use the system.
- An international committee should be established to oversee the author ID initiative and seek to develop it for other benefits for the community.
- There should be a privacy policy developed as part of the system. This would enable individual researchers to define what data can be accessed both via the Web portal and the API.
- The affiliation IDs of the authors should form part of their data so that institutions can access all researchers who work, or have worked, at a given university, research institute and so forth.
- The affiliations of the authors should form part of their data so that institutions can access all researchers who work, or have worked, at a given university, research institute and so forth.
- Publishers should update their workflows so that the author ID is included (and possibly required) and that it is attached to every scientific paper that is submitted. This should include conferences, books, monographs and so forth.
- Work that has already been published should be updated, in the same way that DOIs are now attributed to the vast majority of papers.
- Search facilities on publishing websites should enable users to search by author ID.
- Every author, as well as their name, should also include their author ID as part of the title information on a paper. We would suggest that this is placed in parenthesis after the author's name.
- As well as author IDs appearing on papers, it should appear on other key areas, such as editorial boards, programme committees, external examining roles, funding agency committees and so forth.

-
- A suitable API should be developed so that anybody can access the data in an automated way.
 - The initiative should be managed by a not-for-profit organisation to preclude any conflict of interest and to ensure the sustainability of the project.

We acknowledge that the proposal presented above is a shift change in the way the scientific community operates. There are many hurdles that would need to be overcome and many more discussions that would need to take place, but we hope that these proposals provide the catalyst for change.

8. Discussion

The scientific publishing industry is changing, perhaps faster than it has ever changed before. A lot of the change is being financially driven as publishers, and other providers, seek to adapt to new ways of working and establish new business models so that they remain competitive in the market. This can most obviously be seen in the transition from traditional publishing to open access publishing (Kendall *et al.*, 2015) and in new services that are now being offered (Kendall *et al.*, 2016).

There is also a battle being fought to take control of information, such as publication details, authors, social media and so forth. Various providers have entered the market in recent years, and this is leading to different products which researchers have to register for, and then keep up to date. Moreover, these systems are not providing everything that could be useful to a researcher, and the scientific community, in general, is not being fully consulted.

In this paper, we have argued for a single, independent system that provides every researcher with one identifier, enabling maintenance to be a lot easier, author disambiguation to be a problem of the past and for many additional services to be provided that would be of great benefit to researchers and their institutions. Finally, the system should form part of the workflows of publishers, conference organisers and so forth so that all the data are captured, stored in one place and can be interrogated easily.

9. Conclusion

In almost every aspect of our lives, we are governed by having a unique identifier that discriminates us from everybody else in the system. If this were not the case, then any system would be unworkable and would result in chaos. Yet, the scientific community works within this chaotic system and as the connected, global age has developed, it has exposed its inadequacies. We can no longer rely on name and/or institution to differentiate ourselves. We must move towards each academic having a single identifier. Moreover, we suggest that the community should utilise a single identifier system, rather than having competing systems where, at best, data have to be entered into several places and, at worst, the systems are not integrated or commercial pressures come into play. Therefore, any system that supports this important area of the academic community should be run by a not-for-profit organisation and there should be one system. Of course, there is a need for a sustainable financial model, but that is different to developing a business model that has ultimate responsibility to its shareholders. If the scientific community does not resolve this now, we may get to the point of no return.
